## G&G Disclaimer and General Information

- The material presented is work in progress; during the course of investigation the interpretations have been revised based on data as it becomes available. As such, there are some differences between the slides presented, depending on the stage of revision for each dataset. These differences have been minimised where possible.
- The presentation represents the current view of the authors; this view may change in part or in entirety dependent on the completion of the current drilling and final analyses which are still in progress.
- Where depths are provided these may be approximate or subject to change after final interpretation and revision of the seismic depth-velocity model.
- Spatial locations where quoted are WGS84 datum
- The interpretation is the authors view only, it is not necessarily the view of Timor Resources JV or any other entity associated with the project.

TIMOR PETROLEUM

"OIL IN EVERY HOLE"

The secretaries of Timor Petroleum

Company, Limited, Melbourne, report

the receipt of a letter from the chief

geologist and field superintendent

(Captain L. L. Wrathall) of the com-

pany's concessions in Timor, dated

April 28, in which he states that both

plants have arrived at the island. A

special raft was constructed at Aliam-

bata, and no difficulty was experienced

in unloading the heavy pieces of mate-

rial. A motor truck has been pur-

being conducted satisfactorily. As re-

gards his preliminary examination of

the concessions, Captain Wrathall re-

marks: "I can be cheery about the

oll. It would do your heart good to

see the gas fires burning at night-

time. There is oil in every hole that tesiste

Timor Petroleum

two directors, Messrs. A. J. Staughton and

on May 4), a new working system had

been installed, and it was now hoped

that development would proceed expedi-

operations. The climate was such that

all the staff had suffered from malaria.

No one should be allowed to remain

shares at £1 each, to obtain capital to

tiously and successfully.

out a holiday.

#### Tectono-Chrono-stratigraphy

Bobonaro Mélange (1m horizontal lines)

## Generalised Stratigraphy, Combined 2021-2023 Wells

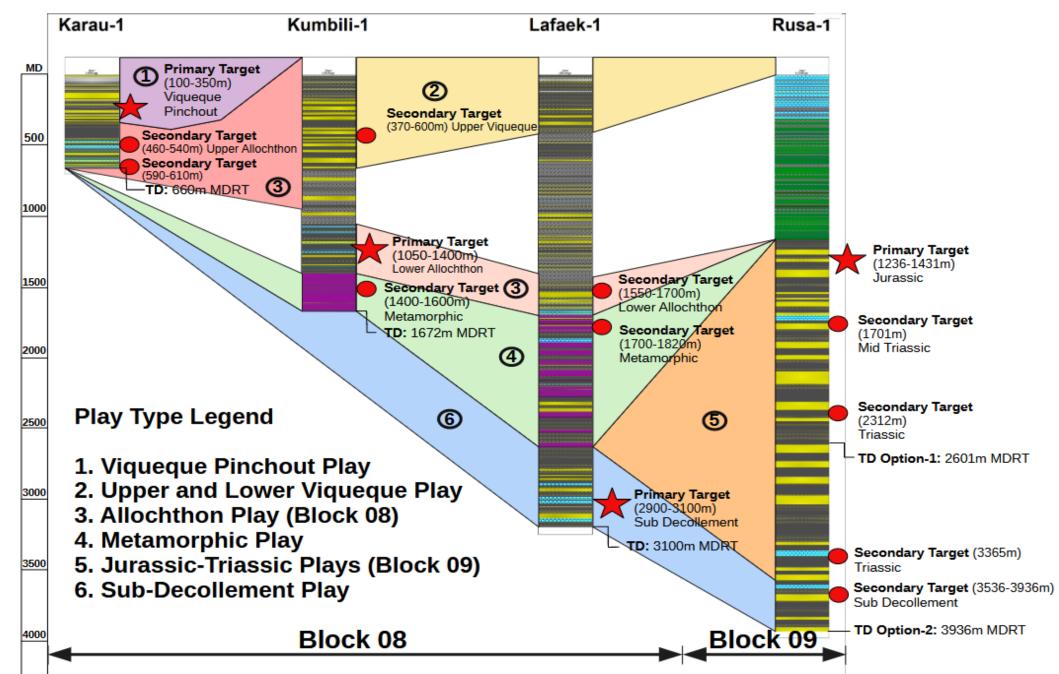

Alluvium Alluvium: Sandstones, Siltstones, Gravels/Boulders. Ainaro Gravel Suai: Silty Claystone, Sandstone, minor Conglomerate and Limestone. Unconsolidated to poorly consolidated Suai Ainaro Gravel: Rounded river Pebble to Boulder gravels, Siltstone, Sandstone; old river beds raised above current river levels. Viqueque (Pliocene-Vigueque: Claystone, Shale, Clayey Siltstones, Sandstone and occasional Conglomerates. Pleistocene) Triassic Bobonaro: Angular to sub-rounded blocks of various ages and lithologies within a matrix of shale; commonly with a scaly texture. This unit may represent a tectonic mélange or extremely deformed foldbelt composed of all BOBONARO components of the Permian to Pliocene section, clays are ductile - soft with montmorillonite content. The origin of the clay is uncertain and probably a combination of diapiric shales and clay from within the disrupted section. Triassic Wai Luli: Grey Shale and blue grey Marl, black organic Shale, Siltstone Aitutu: Limestone, calcilutite, light to dark shale, minor Sandstone and Siltstone. Triassic Babulu : Sandstone, Siltstone and Shale, minor Limestone, turbidites. Upper Palelo: Volcanics, volcaniclastics, breccias, cherts, siliceous argillites, sandstone, limestone. ?Banda Arc UPPER PALELO Lolotoi Metamorphic Complex: Greenstone meta-igneous rocks and meta-sedimentary schists, common graphitic; LOLOTOI predominantly greenschist facies. Moderately hard to very hard. ?Banda Arc WaiLuli Wai Luli: Grey Shale and blue grey Marl, minor black organic Shale, Siltstone Babulu/Aitutu (Triassic) Babulu and Aitutu as above: Sandstone, Shales and Limestones of Triassic age (and possibly Jurassic). Beneath the regional thrust decollement.

#### LAFAEK-1, Dip Line 1994SBT-07 (uninterpreted)

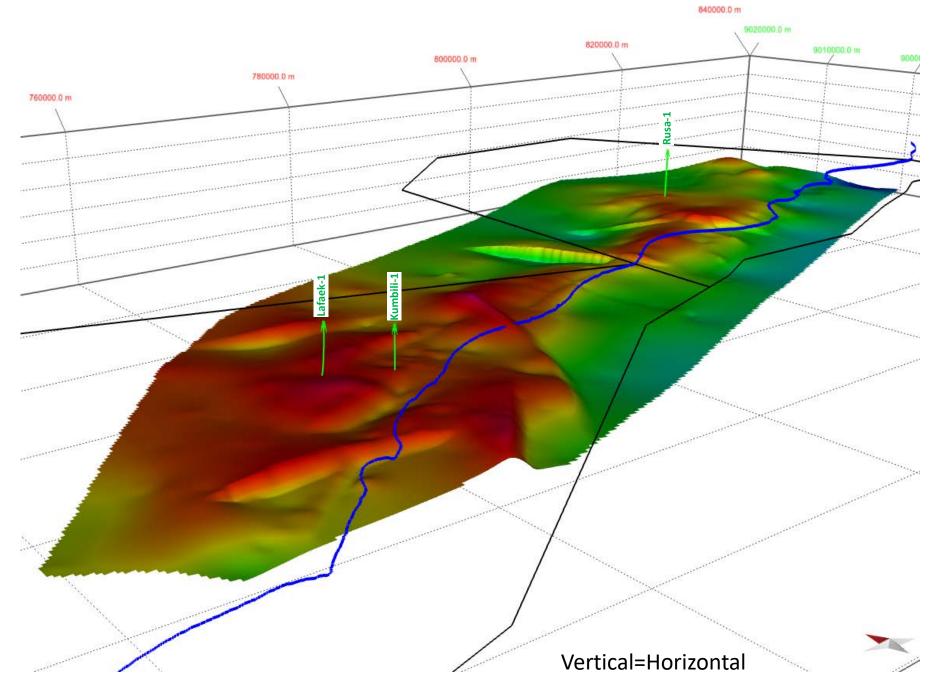

Sub-Decollement

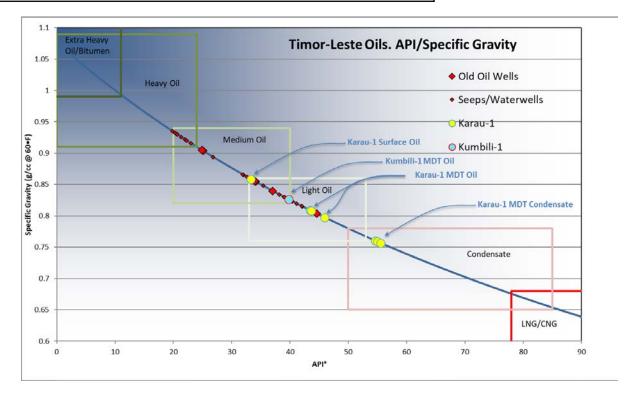

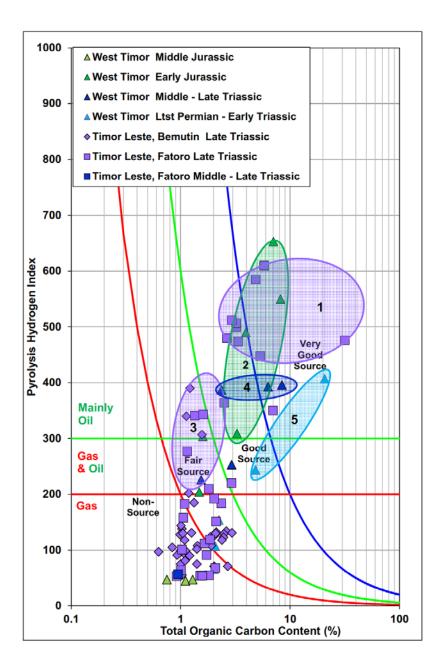

Well	Depth (mMDRT)	Туре	ΑΡΙ	Comment
Karau-1	463	Oil	33.3°	Oil collected at surface in mud
Karau-1	466-467	Oil	43.6°	Mini-DST, matrix
Karau-1	518-519	Gas	54.7°	Mini-DST, fracture
Karau-1	564.5-565.5	Oil	46.0°	Mini-DST, matrix
Karau-1	604.1-605.1	Gas	55.3°	Mini-DST, fracture
Kumbili-1	956.7-957.3	Oil	39.8°	Mini-DST, matrix (filtrate invasion)

The oils are all mobile and range in colour from redbrown to black. The Kumbili- 1 and deepest Karau-1 samples exhibit the lightest colours and are clear. The compositions are consistent with light, unaltered oils of marine origin.

#### Source Rocks

1 – Late Triassic (Norian – Rhaetian) calcareous claystones and limestones from Timor-Leste (Fatoro River). Organically-rich and highly oil-prone

2 –Early Jurassic calcareous claystones and limestones from West Timor. Organically rich and moderately to highly oil-prone

3 – Late Triassic (mostly Rhaetian) highly calcareous claystones from Timor Leste (Bemutin and Fatoro Rivers). Organically leaner than other Late Triassic source rocks and less oil-prone.

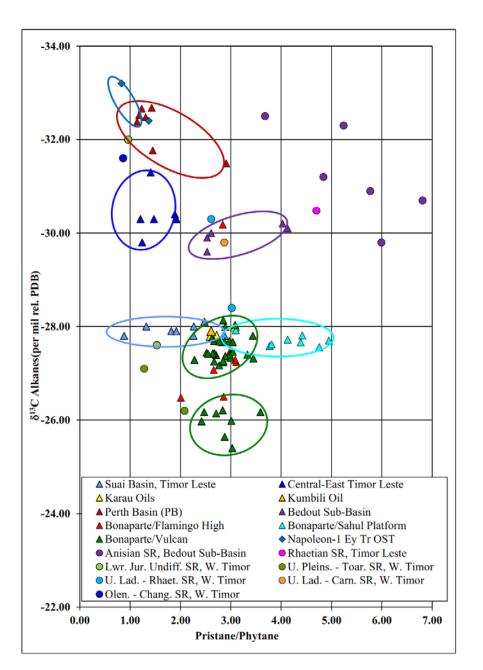

4 – Middle – Late Triassic claystones from West Timor. Organically rich but less oil-prone than Early Jurassic in West Timor or Norian-Rhaetian (1) source rocks from Timor Leste

5 – (?Latest Permian –) Early Triassic claystones from West Timor. Organically rich and moderately to highly oil prone. Age equivalent to Kockatea Shale in the Perth Basin

## **Oil Correlation**

Timor-Leste Oils are all marine-derived algal oils but fall in two distinct groups based on carbon isotopes:

Group I - Suai Basin Oils

Isotopically heavy oils which include Karau and Kumbili oils from recent drilling campaign (plus numerous seeps, Matai, Cota Taci and Suai Loro oils).

Group II – Central and Eastern Seeps

Isotopically light oils including Pualaca and Aliambata oils.

Group II show closest match to Norian - Rhaetian source rocks. Isotopically-light nature is typical of other Triassic sourced-oils on NW Shelf (e.g. Bedout sub-Basin, Perth Basin)

Group I show closest match to Early Jurassic source rocks from West Timor. These oils are isotopically-similar to Early-Middle Jurassic sourced oils from Vulcan sub-Basin, Sahul Platform and Flamingo High.

#### Metamorphic cover sequence

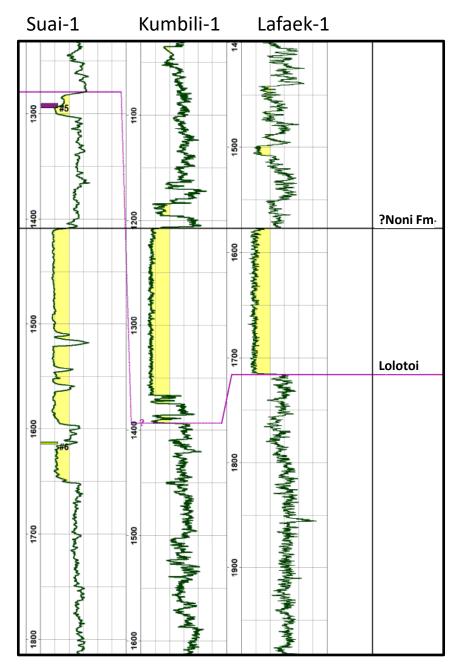

Noni Formation, Palelo Group, Siliceous argillite

(Suai-1, Kumbili-1, Lafaek-1) Dartollu (Cota Taci-1, Matai).

## **Drilling and General Observations**

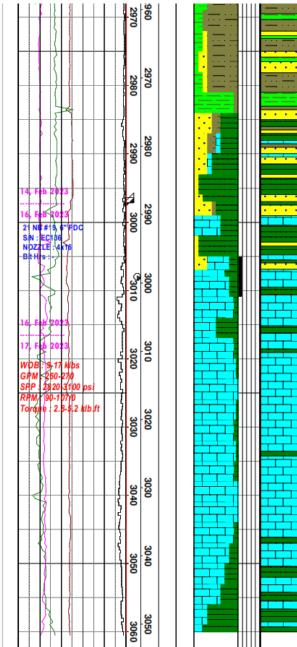

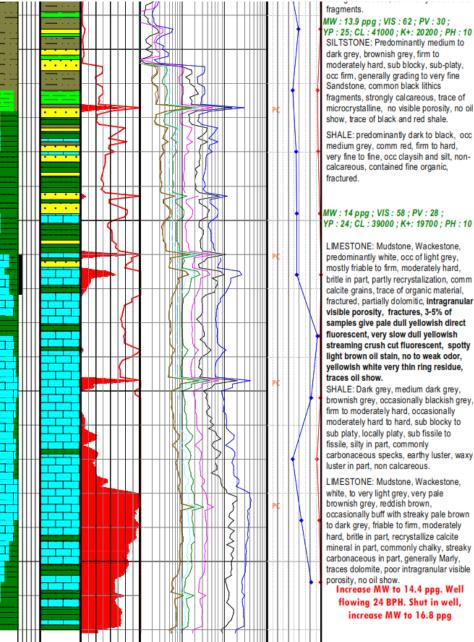

- The drilling of the three wells has been challenging, the main factors being:
  - The Bobonaro clay interval; clay inhibition may have helped but the main defence is high mud weight and regular wiper trips.
  - Over-pressure; pressure can rise significantly and with little warning, vigilance in pressure hunt protocols is necessary as is the ability to mix and pump higher mud weights quickly.
- The prognosed seismic depth for formation changes was better than expected considering the low frequency of the deeper data. The seismic depth/velocity model was updated after each sonic log but there is a large variation in velocity, particularly in the Bobonaro. High Barite content for mud weight impacted on density log with settling in fractures.
- With no drilling supply infrastructure in country, inventories of back-up equipment parts, mud chemicals etc., has to maintained at high levels to compensate for 3+ week lead time on even basic materials.
- Drilling operations are still underway and analysis of results in process.
- Well testing equipment has been mobilised and the resource surety will progress based on those results and then move to Appraisal drilling.

#### Lafaek-1 Update

#### Test zones in 8.5" Section:

2058-2078mMDRT, Sandstone, oil shows, oil on shakers. Highly fractured, matrix porosity 10% 1785 – 1805mMDRT, metamorphic, elevated wet gas / light oil on chromatograph, heavily fractured 1594 – 1625mMDRT, Upper ?Noni Formation, interpreted pay intervals with matrix porosity 8-14%, highly fractured. Light oil / wet gas

#### 6" Section

Drill and connection gas increasing at 2980mMDRT, started increasing mud weight;

Then significant increases at 3040mMDRT; continued increasing mud weight.

At 3060mMDRT, well kicked, shut in, killed with 16.8ppg (~8,800psi formation pressure).

Certification of resources has been provided for 4.2mmbbl recoverable (2C) for Karau and 24.6mmbbl for Kumbili (2C). Lafaek TBA.

The exploration results to date have provided much information to help resolve some long-standing debates; whilst acknowledging that if there is more than one geologist in the room, they will raise many others.

Actively looking for partners for the future
